1.0 INTRODUCTION

This report presents 1996 data for groundwater quality at the Present Sanitary Landfill, Rocky Flats Environmental Technology Site (RFETS). The Present Landfill serves as the solid waste disposal facility for RFETS and is one of three interim status units at RFETS that are regulated under the Resource Conservation and Recovery Act (RCRA). Throughout 1996, groundwater monitoring was conducted in accordance with regulations of the Colorado Department of Public Health and Environment Health (CDPHE), contained in Title 6 of the Colorado Code of Regulations, *6 CCR 1007-2*, and *6 CCR 1007-3*. These codes pertain to solid-waste disposal sites and facilities, and require a determination of the impact of the Present Landfill on water quality in the uppermost aquifer.

Information compiled for the 1997 Landfill Report includes a review of historical activities at the Present Landfill (Section 2.0), a summary of previous investigations (Section 3.0), the status of the current monitoring program (Section 4.0), the current understanding of the physical characteristics of groundwater flow at the site (Section 5.0), an assessment of groundwater quality (Section 6.0), a summary of methane-gas data (Section 7.0), and general conclusions regarding groundwater quality and the groundwater monitoring program at the Present Landfill at RFETS (Section 8.0).

2.0 OPERATING HISTORY OF THE PRESENT LANDFILL

The Present Landfill began operating August 14, 1968, for the disposal of Rocky Flats sanitary waste. However, records indicated that, prior to 1986, some hazardous waste was disposed of at the landfill; therefore, in 1986, the landfill became classified as a RCRA-regulated unit. Disposal of hazardous constituents in the landfill was halted in November of 1986. The landfill has remained in operation and currently is accepting only nonhazardous solid waste. The following paragraphs provide a brief historical summary of the landfill.

In September 1973, tritium was detected in leachate draining from the landfill. In response to this detection, a sampling program was initiated to determine the location of the tritium source. In addition, radiation monitoring of waste prior to burial was initiated to prevent further disposal of radioactive material, and interim-response measures were undertaken to control the generation and migration of landfill leachate. Interim-response measures included the construction of two ponds (Ponds No. 1 and No. 2, also known as the West Landfill Pond and East Landfill Pond, respectively) immediately east of the landfill, and the installation of a subsurface leachate-collection system and subsurface intercept system for diverting groundwater around the landfill. Ditches were also constructed to control surface water.

The West Landfill Pond embankment was built approximately 500 ft east of the 1974 position of the advancing face of the landfill. The East Landfill Pond embankment was constructed approximately 1,000 ft east of the West Landfill Pond embankment. A cutoff wall, set in bedrock, was constructed in the East Landfill Pond embankment to reduce seepage through the embankment foundation. The embankments and ponds were built to collect and evaporate groundwater, surface water, and leachate collected by the subsurface drainage-control system.

The leachate-collection system and groundwater-intercept/diversion system were constructed around the west, north, and south perimeters of the landfill. The leachate-collection system was

designed to provide a perimeter drain for landfill leachate to prevent migration of leachate and to reduce water levels in the landfill. The groundwater-intercept/diversion system was constructed along the outside edge of the collection system to prevent groundwater from entering the landfill area. Groundwater is diverted from the landfill toward the East Landfill Pond.

Between 1977 and 1981, the leachate-collection system was covered with waste as the landfill expanded beyond the limits of the system. The west embankment and West Landfill Pond were removed in 1981, and two slurry walls were constructed, extending from the ends of the north and south groundwater-interceptor ditches. These slurry walls range in depth from 10 ft to 25 ft, and were seated in bedrock.

Sometime after the Present Landfill went into operation in 1968, excess water from the landfill pond was sprayed onto a ridge south of the East Landfill Pond. The sprayed water collected on the roadway and flowed into North Walnut Creek. When this misdirected flow was discovered, the spraying activities were moved to an area north of the landfill pond adjacent to an irrigation ditch. Because the subsequent spray water then collected in local drainage channels and flowed around the landfill pond to the main drainage, the spraying activities were again moved. The final spray location was an area south of the west end of the landfill pond, excess spray water flowed back into the East Landfill Pond.

After groundwater within the landfill discharges to the Landfill Pond, it is retained within the pond, where it evaporates. Subsurface leakage of the pond may also occur, which would recharge the unconsolidated deposits below the landfill pond dam.

Groundwater monitoring was instituted in 1989 in accordance with *6 CCR 1007-2* and *6 CCR 1007-3, Subsection 265.90(d)*. This report addresses monitoring requirements pertaining to solid-waste disposal sites and facilities (*6 CCR 1007-2*). Monitoring pertaining to hazardous-waste sites (*6 CCR 1007-3*) are addressed in the Annual RCRA Groundwater Monitoring Reports (U.S. Department of Energy [DOE], 1990, 1991, 1992, 1993, 1994, 1995, and 1996). The regulations

require that the groundwater monitoring program be capable of determining the impact of a facility on the water quality in the uppermost aquifer. At least one well must monitor groundwater quality upgradient of the RCRA unit, and at least three wells must monitor groundwater quality at the downgradient point-of-compliance of the RCRA unit.

The Annual RCRA Reports for RFETS describe chemical and physical aspects of groundwater (for 1989 through 1995) at the Present Landfill (DOE, 1990, 1991, 1992, 1993, 1994, 1995, and 1996). The *Phase I RCRA Facility Investigation/Remedial Investigation (RFI/RI) Work Plan for Operable Unit 7 – Present Sanitary Landfill* (DOE, 1991) presents additional information regarding construction, operation, regulatory history, and site characterization. Work conducted for Phase I included cone penetrometer testing, soil sampling, and the installation and sampling of additional groundwater monitoring wells.

3.0 SUMMARY OF PREVIOUS INVESTIGATIONS

3.1 Description of Previous Investigations

Annual RCRA Groundwater Monitoring Reports from 1989 through 1996 describe groundwater elevations and flow rates, as well as the results of the groundwater analyses. The sampling and analysis records were maintained in compliance with *6 CCR 1007-3* and *40 CFR 265.94(b)*. The *Phase I RFI/RI Work Plan for OU7 – Present Sanitary Landfill* (DOE, 1991b) and the Operable Unit 7 Revised Draft Interim Measure/Interim Remedial Action (IM/IRA) Decision Document and Closure Plan (DOE, 1996b) present additional information.

The nature and extent of groundwater contamination at the Present Landfill have been evaluated in previous Annual RCRA Groundwater Monitoring Reports (DOE, 1990, 1991, 1992, 1993, 1994, 1995, 1996a, 1996b). In 1992, groundwater from surficial deposits within and around the Present Landfill had concentrations of major anions (bicarbonate, chloride, nitrate/nitrite, sulfate), total dissolved solids [TDS], dissolved metals (calcium, chromium, lithium, magnesium, potassium, sodium, and strontium), and radionuclides that were elevated relative to mean background concentrations/activities. Some volatile organic compounds (VOCs) were also detected. The dissolved radionuclides present included americium-241, plutonium-239+240, uranium-233+234, uranium-238, and radium-226. Throughout 1992, concentrations of dissolved metals and radionuclides were only rarely greater than mean background concentrations.

During 1992, VOCs were detected sporadically and infrequently in wells screened in surficial materials of the upper hydrostratigraphic unit (UHSU). In UHSU bedrock, VOCs were detected in groundwater sampled from two wells. Methylene chloride, acetone, and toluene were detected once. The infrequent occurrence of VOCs in the UHSU bedrock indicated that the Present Landfill had not adversely impacted groundwater in UHSU bedrock, even though some contamination of groundwater had occurred in UHSU surficial materials overlying the bedrock.

In 1993, the groundwater chemistry at the Present Landfill appeared generally consistent with water-quality conditions of 1992 (DOE, 1994a). The 1993 statistical comparisons of upgradient versus downgradient UHSU groundwater at the Present Landfill indicated statistically significant increases in downgradient concentrations of dissolved metals (calcium, lithium, magnesium, potassium, sodium, and strontium), and major anions (chloride and sulfate). None of the radionuclides or VOCs showed a statistically significant difference in upgradient versus downgradient activities or concentrations, respectively. Radionuclide activities and concentrations of VOCs, metals, and anions were notably highest within the landfill and in the area adjacent to Individual Hazardous Substance Sites (IHSSs) located southeast of the landfill, relative to other areas in the vicinity of the Present Landfill. In groundwater from UHSU bedrock beneath and downgradient of the landfill, VOCs were detected infrequently, but radionuclides were present at activities higher than mean background.

Analysis of 1994 data by analysis of variance (ANOVA) indicated statistically significant differences in upgradient versus downgradient groundwater quality in the total UHSU for radionuclides (uranium-233 + 234 and uranium-238), dissolved metals (calcium, lithium, magnesium, sodium, and strontium), anions (carbonate, chloride, fluoride, and sulfate), and TDS (DOE, 1995). In the UHSU bedrock, there were statistically significant differences in upgradient versus downgradient groundwater quality for dissolved metals (calcium, lithium, magnesium, sodium, and strontium), anions (bicarbonate, chloride, and sulfate), and TDS. All VOCs had less than 50-percent quantifiable results.

For 1995, statistical comparisons of upgradient versus downgradient UHSU groundwater at the Present Landfill indicated statistically significant increases in levels of dissolved barium, calcium, lithium, magnesium, silicon, sodium, strontium, uranium-233 + 234, and gross beta, as well as bicarbonate, chloride, sulfate, and TDS. Activities of total americium-241, plutonium-239 + 240, and tritium did not show statistically significant difference between upgradient and downgradient UHSU groundwater. All VOCs were detected in fewer than 50 percent of the samples, so these analytes were not statistically evaluated.

Conditions at the Present Landfill in 1995 appeared generally consistent with those of 1994; in 1994 there were 15 inorganic parameters with significant differences in concentrations up and downgradient of the Present Landfill. In 1995, 16 inorganic parameters displayed significant differences. Contaminants detected in monitoring wells southeast of the Present Landfill may be due to an inadequately functioning groundwater-intercept system in this area, emplacement of wastes beyond the limit of the intercept system, or impacts associated with other IHSSs adjacent to the landfill. Organic contaminants appear to be migrating from an upgradient source, perhaps IHSS 174, with a plume that is traversing along and through the southern portion of the Present Landfill.

3.2 Conclusions of Previous Investigations

Results of hydrogeologic investigations of the Present Landfill suggest that the groundwater-intercept system may not completely isolate the landfill from the surrounding groundwater. Hydraulic assessments for specific areas on the west, north, and south sides of the groundwater-intercept system indicate that groundwater may flow into the landfill on the west or northwest and may be exiting the landfill near the southwest boundary at some times during the year.

Previous reports indicate that buried landfill wastes extend beyond the leachate-collection system. Therefore, leachate generated outside the leachate-collection system could be collected by the groundwater-diversion system. In addition, the clay cutoff wall no longer extends to the surface of the landfill; this would allow groundwater to flow across the clay cutoff wall if the water table were to rise sufficiently. Landfill wastes do not extend to the surface-water interceptor ditch.

An evaluation of groundwater-elevation data for 1991 through 1995 indicates that previous conclusions made regarding the impact of the leachate/groundwater-intercept system are still valid. These conclusions are:

- The groundwater-intercept system diverts groundwater away from the west end of the landfill.
- The groundwater-intercept system does not divert all groundwater from the north and south sides of the landfill.
- The clay barrier is an effective barrier to groundwater flow in the landfill along the west and north sides.
- The clay barrier does not appear completely effective on the south side of the landfill, and may allow groundwater to enter the landfill at times.
- The groundwater-intercept system appears to function intermittently on the north side of the landfill.

4.0 CURRENT GROUNDWATER MONITORING PROGRAM

The Present Landfill at RFETS currently operates under CDPHE and Environmental Protection Agency (EPA) guidelines for solid waste disposal sites and facilities and accepts only nonhazardous waste. The groundwater-monitoring program was instituted in accordance with State regulation *6 CCR 1007-2*. Recent changes to the site groundwater monitoring program are outlined in the Draft Integrated Monitoring Plan (IMP) (DOE, 1997). This plan includes the monitoring program for the Present Landfill including sampling, analysis, and reporting. Operating procedures are used to specify techniques for sample collection, preservation, shipment, and chain-of-custody control.

A closure plan for the Present Landfill was developed in the IM/IRA decision document (DOE, 1996), in accordance with the Rocky Flats Cleanup Agreement (RFCA) (RFCA, 1996) and applicable Colorado hazardous-waste regulations. Due to the Present Landfill's position (25) on the Environmental Restoration Ranking (DOE 1996) action has been deferred until higher ranked areas are remediated. Post-closure inspection, maintenance, and monitoring of the Present Landfill will be performed in accordance with *6 CCR 1007-3, Part 265, Subpart G*.

In a letter from CDPHE dated February 13, 1995, DOE received approval to discontinue groundwater monitoring of 27 monitoring wells that lie within the interior of the Present Landfill. These wells were identified as needing abandonment in preparation for a remedial cover that was to be constructed over the main landfill area. Pursuant to a written directive from the Operable Unit 7 (OU7) manager, these 27 wells were eliminated from the monitoring program in the second quarter of 1995. The elimination of these wells makes it no longer possible to construct potentiometric-surface maps and concentration-isopleth maps; the current and future reports will only assess impacts to or from the landfill on the landfill boundaries.

As a result of the deactivation of interior wells in the second quarter of 1995, samples were not collected from all previously active wells at the Present Landfill. For the current report, upgradient wells at the Present Landfill (70093, 70193, 70393, 70493, and 5887) were sampled,

and downgradient wells (4087, 52894, 52994, B206989, 53194, 6687, 76992, and 77392) were also sampled. Table 4-1 shows the hydrostratigraphic unit monitored and material screened for all wells in and near the Present Landfill. Wells 0786, 0886, 6087, 6187, 6287, 6487, 6587, 6887, 7087, 7287, B106089, B206289, B206389, B206489, B206589, B206789, 00393, 71193, 71493, 71693, 71893, 72093, 72293, 72393, and 72493 have been deactivated.

Groundwater elevations for active wells were measured at least quarterly; however, the quarterly collection of groundwater samples was suspended in November, 1996 when the new groundwater monitoring plan was instituted. Groundwater samples were analyzed for radionuclides, volatile organic compounds (VOCs), dissolved metals, and major anions. Table 4-2 lists the analytes collected during monitoring, as well as some additional analytes. Concentrations and spatial distributions of selected analytes are depicted on maps (Figures 4-1 - 4-4). Results of methane-gas monitoring at four groundwater wells (6687, 71693, B106089, 6287) screened within and adjacent to the landfill are presented in Section 7.0. These four wells have since been abandoned as part of the Well Abandonment and Replacement Program (WARP). Well 6687 was replaced by new well 00597 which may be used for methane monitoring in the future. The records of analyses and evaluations are maintained in compliance with 6 CCR 1007-2.

5.0 PHYSICAL CHARACTERISTICS OF THE GROUNDWATER SYSTEM

5.1 Description of the "Uppermost Aquifer"

The "uppermost aquifer" is equivalent to the UHSU as described in recent RFETS reports (EG&G, 1995a, 1995b, and 1995c). In the area of the Present Landfill, the UHSU is composed of unconsolidated surficial deposits and weathered bedrock. The unconsolidated deposits consist of Rocky Flats Alluvium, colluvium, and valley-fill alluvium. The Rocky Flats Alluvium and artificial fill (landfilled wastes and soil-cover materials) are present upgradient of and within the landfill, respectively; colluvium and valley-fill alluvium are present downgradient of the Present Landfill. Weathered claystones and weathered sandstones that are in direct hydraulic contact with the overlying surficial deposits, are also considered part of the uppermost "aquifer". The weathered claystones are generally more permeable than unweathered bedrock.

UHSU Surficial Materials and Bedrock
1996

Unweathered claystones are not considered as part of the uppermost "aquifer", rather they are included as part of the LHSU. Bedrock wells were assigned to a hydrostratigraphic unit based on geochemical data from the well, hydraulic conductivity measurements (where available), and information from borehole logs.

5.2 Potentiometric Surface

Groundwater is present in surficial deposits and artificial fill, and in bedrock sandstones and claystones in the area of the Present Sanitary Landfill. Within landfill wastes, groundwater flows toward the center of the landfill, then flows east toward the face of the landfill. Outside the landfill, groundwater generally flows eastward within saturated UHSU surficial deposits, toward the landfill pond. Near the East Landfill Pond, however, groundwater flows from the north, west, and south toward the pond.

Groundwater elevations are measured at least quarterly, and these elevations in the surficial deposits of the UHSU are characterized by seasonal variations of as much as 10 feet. The water-table elevation is generally lowest in late winter and early spring prior to recharge by snowmelt, and highest during June and July. Groundwater elevations in the weathered bedrock of the UHSU typically show seasonal variations of as much as 15 feet (DOE, 1992b).

5.3 Vertical Hydraulic Gradients

Vertical hydraulic gradient is the quotient of the differences in water levels measured concurrently in two adjacent wells, and the vertical distance between the two measuring points, which are specified here as the midpoint of each screened interval. Vertical gradients were calculated at 12 well pairs in 1995. Only two of these pairs remained active for 1996. Examination of historic water level data indicates that hydraulic gradients remain generally consistent over time barring extreme climatic events. Therefore, the 1995 gradient calculations have been presented here to provide a more complete summary (Table 5-1). Wells with

overlapping screened intervals were not used to calculate vertical hydraulic gradients.

With one exception (well pair 72393/72093 in the center of the landfill), the calculated vertical gradients were all directed downward. The calculated upward vertical gradient at 72393/72093 was approximately 0.020 to 0.026 for the first three quarters of 1995. Downward vertical gradients ranging from 0.022 to 1.099 were calculated for the remaining well pairs. In general, the magnitudes and directions of gradients measured at the landfill in 1995 were similar to those calculated for 1994.

5.4 Average Linear-Flow Velocities

The average linear groundwater-flow velocity was calculated for three flow-paths in UHSU surficial deposits and three flow-paths in UHSU bedrock in the vicinity of the Present Landfill for 1995. Most of the well pairs used had been deactivated for 1996. However, the variables used in calculating flow velocities (hydraulic conductivity, porosity, and hydraulic gradient) remain effectively constant over time. Hence, the following discussion excerpted from the 1995 report is considered indicative of current conditions in the Present Landfill.

Migration rates for conservative, dissolved constituents approximate the average linear groundwater-flow velocity; however, attenuated, volatile, biodegradable, or redox-sensitive species probably exhibit migration rates less than the average linear groundwater-flow velocity. Table 5-2 presents the calculated average linear velocities of groundwater flow during the first three quarters of 1995.

The values of hydraulic conductivity used for surficial deposits and bedrock of the UHSU are the geometric means of hydraulic-conductivity values for each unit at the Present Landfill, and include results of historic slug tests (DOE, 1994a). The value of hydraulic conductivity used for surficial deposits (including landfill wastes) is 1.1×10^{-4} cm/sec. RCRA reports prior to 1993 used a hydraulic-conductivity value of 3.1×10^{-4} to 3.8×10^{-4} cm/sec. The value of hydraulic

^b Geometric mean of hydraulic conductivity values at the Present Landfill (preliminary results of OU7 RFI/RI)

^c n = assumed effective porosity (EG&G, 1993)

^d v = Darcy velocity (average linear groundwater-flow velocity)

^e = Gradient calculated under non-equilibrium conditions. Reported values are given as estimates only.

conductivity used for bedrock of the UHSU is 5.33×10^{-7} cm/sec, which is also slightly lower than the value used in reports prior to 1993 (8.9×10^{-7} cm/sec). The assumed effective porosity for all units is 0.1 (DOE, 1991a). In 1995, the calculated flow velocities for groundwater in UHSU surficial materials were similar to those for 1994.

Calculated average linear-flow velocities in fill materials range from approximately 1 foot per year at the west end of the landfill to approximately 160 feet per year at the advancing eastern face of the landfill. Calculated average linear-flow velocities in UHSU bedrock at the Present Landfill ranged from approximately 0.20 feet to 0.22 feet per year beneath the landfill, to approximately 0.07 feet to 0.41 feet per year downgradient of the landfill. The calculated groundwater-flow velocities for UHSU bedrock in 1995 were similar to those reported in the 1994 Annual RCRA Groundwater Monitoring Report (DOE, 1995).

6.0 GROUNDWATER QUALITY IMMEDIATELY DOWNGRADIENT OF THE PRESENT LANDFILL

Statistical comparisons between downgradient and upgradient groundwater data were made using the methodology described in the *1995 Annual RCRA Groundwater Monitoring Report* (DOE, 1996). The assessment of groundwater chemistry at the Present Landfill includes a statistical evaluation of the chemistry of downgradient groundwater with respect to upgradient groundwater, and an evaluation of the spatial distribution of groundwater constituents in and around the landfill.

Analytes were placed into groups based on the percentage of quantified results (detections) obtained from laboratory testing. Meaningful statistical analyses cannot be performed for analytes that are rarely detected. All analytical data are presented in Appendix A of this report.

Table 6-1

6.1 Statistical Comparison of the Chemistry of Upgradient and Downgradient Groundwater

Where possible, analytical data for groundwater monitored upgradient of the Present Landfill were compared statistically to analytical data for groundwater sampled from compliance-boundary wells located downgradient of the Present Landfill. Results of these comparisons were used to evaluate potential contaminant releases from the regulated unit into the uppermost "aquifer". The comparisons between upgradient and downgradient groundwater quality were made using the statistical methodology discussed in the 1995 Annual RCRA Report (DOE, 1996). Due to the reduced frequency of sampling, well deactivations, and lack of water in downgradient wells, the majority of analytes had insufficient data to perform statistical analyses for 1996. Concentration ranges for detected analytes in downgradient wells have been presented in (Table 6-2). Individual concentrations for analytes detected in downgradient wells have also been posted in box charts figures 4-1 through 4-4. All VOC detections both upgradient and downgradient are included.

At the Present Landfill, five wells (5887, 70093, 70193, 70393, and 70493) monitor groundwater chemistry in the UHSU immediately upgradient of the Present Landfill. Of these wells, three are completed in UHSU surficial materials (wells 5887, 70093, and 70393), and two (wells 70193 and 70493) are completed in UHSU bedrock. Three wells located east of the East Landfill Pond embankment have been used to monitor the chemistry of downgradient groundwater in the UHSU (wells 4087, B206989, and B207089). Note that well B207089 has been deactivated. Three additional downgradient wells (52894, 52994, and 53094) were installed in 1994; these wells monitor groundwater in UHSU surficial materials, UHSU bedrock, and LHSU bedrock, respectively. Well B206989 monitors groundwater in the UHSU bedrock and well 4087 monitors groundwater quality in UHSU surficial materials. However, because the dam for the East Landfill Pond depresses the potentiometric surface to the east, well 4087 is frequently dry. All of the well locations are consistent with 6 CCR 1007-2, which allows alternate placement of monitoring wells downgradient of an interim-status facility where existing physical obstacles prevent installation of wells at the boundary.

Wells 6687 and 76992 are located along the southern and southeastern perimeter of the landfill respectively. Well 77393 is located south of the main access road and was consistently dry in 1996. Well 76992 was also consistently dry. Sample results for well 6687 show detectable concentrations for organic compounds 1,1,1-trichloroethane, 1,1-dichloroethene, carbon tetrachloride, chloroform, tetrachloroethene, and trichloroethene. The source of these VOCs is believed to be the plume associated with IHSSs upgradient of the landfill including the PU & D yard (IHSS 174). Investigative activities for this unit are scheduled to begin in 1997. Detected analytes for well 6687 are presented in table 6-3.

Statistical comparisons were not performed for analytes with less than 50-percent quantifiable results or for analytes with less than three quantifiable results. Dissolved barium, calcium, lithium, magnesium, potassium, selenium, and sodium were each detected twice in UHSU groundwater downgradient. Dissolved radionuclides gross alpha, gross beta, radium-226, uranium-234, uranium-235, and uranium-238 were also each detected twice downgradient (all radionuclide results are considered detects according to the General Radiochemistry and Routine Analytical Services Protocol GRRASP). Americium-241, plutonium-238, and plutonium-239/240, were each detected in one downgradient unfiltered sample. All results for unfiltered radionuclides were "J" qualified by the laboratory (estimated below the detection limit). Anions bicarbonate, chloride, sulfate, and total dissolved solids were each detected twice downgradient.

Results for groundwater from UHSU bedrock downgradient show that chloroform was the only detected analyte, occurring in well B206989. The "J" qualified result of 0.2 UG/L is well below the detection limit of 1.0 UG/L. Unless verified by subsequent analyses, these infrequently detected analytes are not considered to indicate contamination. The detected concentration ranges for all infrequently detected analytes are reported in Table 6-2.

For analytes with greater than 50-percent quantifiable results, ANOVA testing was performed. All UHSU results (alluvial and bedrock) were grouped to provide adequate data to perform

statistical tests. Even so, data were sufficient in number to evaluate only nitrate and tritium statistically. Test results indicated no statistically significant difference (at the 5-percent significance level) in upgradient versus downgradient groundwater quality in the total UHSU for tritium and nitrate. ANOVA results are summarized in table 6-4. All VOCs had less than 50-percent quantifiable results.

7.0 METHANE GAS IN SELECTED MONITORING WELLS AT THE PRESENT LANDFILL

Monitoring of methane gas was performed at four wells in the Present Landfill Area (6287, 6687, 71693, and B106089). Monitoring was done in conjunction with the routine gas monitoring of wells specially constructed for methane monitoring. Wells were selected on the basis of their proximity to the landfill materials, and on having screened intervals within landfill materials above the water table. These four wells were abandoned in 1997 as part of the WARP. Well 6687 was replaced by new well 00597 which may be used for methane monitoring in the future. Wells 44292, 22392, 44492, 44592, and 44692 were previously deactivated and are no longer sampled.

Methane measurements were made on March 29, June 25, and October 1 of 1996, using a Bacharach Sentinel 44 instrument. Measurements are given as a percentage of the lower explosive limit (LEL) and can be found in Table 7-1. Instrument readings indicate that wells 6287 and 71693 had detectable levels of explosive gas. For all quarters, O₂ readings at the one-foot and ten-foot distances ranged from 20.9 to 21.0%.

8.0 CONCLUSIONS

Groundwater in the vicinity of the Present Landfill generally flows to the east, with the flow components converging toward the East Landfill Pond. Within the landfill in 1995, as in 1994, groundwater elevations were slightly higher on the north side than on the south side of the landfill, suggesting that the groundwater-diversion system performs more effectively on the southwest side of the landfill than on the northwest side. It is believed that these general physical

BZ = Breathing Zone Measurement

WB = Well Bore Measurement

characteristics of the groundwater system change little over time barring dramatic climatic or geologic events and remain applicable for this and future reports.

Due to the reduced frequency of sampling, well deactivations, and lack of water in downgradient wells, there were insufficient data to perform statistical analyses for most analytes in 1996. Statistical comparisons of upgradient versus downgradient UHSU groundwater at the Present Landfill were performed, however, for tritium and nitrate. Neither of these constituents displayed statistically significant difference when compared using ANOVA. All VOCs were detected in fewer than 50 percent of the samples, so these analytes were not statistically evaluated.

Conditions at the Present Landfill in 1996 appear generally consistent with those of 1995. However, most results must be described qualitatively for lack of statistical evaluation. Analytes and concentration ranges detected in UHSU groundwater downgradient were consistent with those found in 1995 with the exception of chromium which was detected once in 1996 in well 4087. Graphical examination of concentration ranges (Table 6-2) indicates that lithium, chromium, selenium, sodium, bicarbonate, and chloride as well as gross alpha, gross beta and uranium-234 may be elevated for upgradient versus downgradient wells. This is also consistent with results of statistical analyses performed for 1995 with the exception of selenium. Both detected results for selenium downgradient in 1996 were qualified "N" by the laboratory indicating that spike recovery results were outside control limits.

Contaminants detected in monitoring wells southeast of the Present Landfill may be due to an inadequately functioning groundwater-intercept system in this area, emplacement of wastes beyond the limit of the intercept system, or impacts associated with other IHSSs adjacent to the landfill. Organic contaminants appear to be migrating from an upgradient source, perhaps the PU&D yard (IHSS 174), with a plume that is traversing along and through the southern portion of the Present Landfill.

As discussed in Section 4.0, the sitewide groundwater-monitoring network has been revised, which resulted in fewer wells sampled at the Present Landfill during 1996. Although the number of wells evaluated for this and future Present Landfill reports is less than that of 1995 and earlier reports, it is believed that sufficient upgradient and downgradient wells were sampled to meet or exceed regulatory requirements. It appears that site conditions (dry wells) have prevented the collection of sufficient downgradient data during 1996 to perform statistical analysis for many analytes.
